

### Alfalfa Varietal Experiment

Table No. 3 gives the yield performance of seventeen alfalfa varieties grown at Alfalfa for the years 1965 - 1968 inclusive. Table No. 9 presents the yield performance for the alfalfa varieties grown at the Redmond location from 1965 - 1968.

Table No. 10 shows the average yield for the first four years of production for the included varieties in three recent varietal yield trials, namely, Alfalfa, Redmond, and the Wendall Gross location. The data indicates a relatively small difference in yield when the hardy Vernal types or the hardy Flemish types (alfalfa) are compared. Cayuga was not included at the Gross location, but averaged out to be the highest yielding of the Alfalfa and Redmond nurseries. Cayuga is apparently a slow starter with its strength showing during the third year of production. The recognized dry land or pasture types are generally a little lower yielding than the hay types as would be expected and the less hardy flemish and common alfalfas are not adapted to Central Oregon conditions as shown by the yields of Lahontan, Talent, Sacheville, Cody, DuPuits and Moapa (not shown).

The 1968 crop first and second cuttings of the Alfalfa and Redmond locations are shown in Appendix Tables No. 6, 7, 8, and 9 respectively.
