

**Report to the Oregon Processed Vegetable Commission
1992-1993**

1. Title: Green Bean Breeding
2. Project Leaders: J. R. Baggett, Horticulture
Brian Yorkey, Food Science and Technology
Dan Farkas, Food Science and Technology
3. Project Status: Terminating June 30, 1993
4. Project Funding: \$39,000 breeding
\$25,000 breeding supplementary technical support
\$14,355 processing

Breeding funds were used for a major portion of the support of two vegetable breeding technicians, student labor, supplies, and research farm expenses. Processing funds were used for processing samples of experimental beans, laboratory analysis, and panel evaluations.

5. Objectives: Breed bush green beans for the western Oregon processing industry with:
 - A. Improved potential for high yields at favorable sieve sizes and dependability
 - B. Improved straightness, texture, and other quality factors
 - C. Develop easy picking and small pod strains of Blue Lake type
 - D. Resistance to white mold and root rot
6. Report of Progress:
 - A. Performance and quality of advanced breeding lines were tested in seven replicated yield trials, planted about every 10 days from May 6 to July 8. Trials 2, 4, 5, 6, and 7 included eight OSU varieties and lines along with four commercial varieties of the small sieve or "baby bean" type for comparison with OSU baby bean line 5446. Trials 1 and 3 included seven additional new OSU lines, two of which were omitted from harvest. Since several OSU lines were of the easy picking type, the variety Easy Pick was included in all of the seven trials. The 1992 trials included OSU 5402 (now Oregon 54) compared with related lines, with Oregon 91G as standard control. Plots were 20' long, replicated four times. From one to five five-foot harvests were made from each plot, usually at two-day intervals. Samples were taken, according to plan, to Food Science and Technology for canning and freezing. Processed quality data will be presented in a supplemental report.

When the detailed data on yield of standard size beans (Tables 1-3) were used to calculate \$/acre, it was not possible to make totally valid comparisons between variety means because they were not derived from a uniform number of harvests or uniform maturity at harvest. When the average \$/acre shown in Table 4 was used for comparison, Oregon 91G was lowest compared to the newer lines OSU 5402, 5256, 5416, and 5421. When harvests were selected for closeness to 50-55% 1-4 sieve, shown as Selected \$/A in Table 4, or when the highest value harvest for each variety was used, the results were similar. A summary of these results is as follows:

Variety	Season Average \$/A Based on		
	Trial Averages*	Selected Harvest	Highest Harvest
Oregon 91G	1376	1402	1474
OSU 5256	1413	1433	1537
OSU 5402	1531	1609	1682
OSU 5416	1560	1591	1663
OSU 5421	1697	1757	1807
OSU 5445	1469	1488	1628
OSU 5520	1154	1472	1522

*Average of 1-3 harvests from seven trials.

OSU 5402 values were \$155, \$207, and \$208 higher than those of Oregon 91G, and OSU 5256 also exceeded Oregon 91G. The highest yielding line was 5421, which was as much as \$300 higher than Oregon 91G. It was noted during the season that OSU 5421 seemed to be much less affected by hot weather. OSU 5416 and 5421 should be continued in tests. However, as Table 7 shows, OSU 5421 had the highest score for white mold infection.

Of the newer standard lines, several, but especially OSU 5545, had good \$/acre values but were not consistent. Several of these lines, including 5520, 5545, 5556, 5558, and 5566 are of the easy picking type.

Small sieve variety performance is shown in Table 5. In calculating \$/acre, 2-, 3-, and 4-sieve pods were assigned the same value, \$300/ton. Actual value of these sizes may vary among the processing companies. Giving equal value to 2-, 3-, and 4-sieve pods results in the highest \$/acre values occurring at the more mature stages, which may not be the most profitable stage for the processors. Assuming these varieties are grown to increase the percentage of 3-sieve pods in the annual pack, and that 3-sieve pods are most important, the harvest with the largest tonnage of 3-sieve pods has been starred on Table 5. This harvest was usually, but not always, the last one of the planting date. In the next column, a # marks the harvest with the highest percentage of 3-sieve pods. In trials 1 and 3, the highest value for 76-110 was not used because the 3-sieve pods had become seedy. Season averages based on these two methods of comparison are as follow:

Variety	Season Average \$/Acre Based on	
	Highest T/A 3-sieve	Highest % 3-sieve
OSU 5446	1816	1524
76-110	1191	1112
Dandy	1760	1705
Teseo	1436	1143
Banquet	1451	1277

It should be recognized that the above figures do not reflect the quality of the 3-sieve pods, which is assumed to be the same in all harvests. This was generally observed to be true except in the case of 76-110, trials 1 and 3, as noted above. Of the five varieties included, only OSU 5446 and Rogers-NK 76-110 are sufficiently typical of Blue Lake beans in color and flavor to be packed with Oregon 91G. Dandy, while an excellent producer of small sieve beans, has unacceptably light color for Blue Lake markets. OSU 5446 produces a higher percentage of 4-sieve (compared to 3-sieve) than Dandy and 76-110. OSU 5446 pods are short, slightly curved, and somewhat oval, but have excellent color, smoothness, and flavor.

- B. Tables 6 and 7 show root rot and white mold infection scores for the lines included in the yield trial and a few new breeding lines. Oregon 54 averaged 5.75 compared to 5.0 for Oregon 91G in the white mold test (0 = no infection, 10 = complete infection), while OSU 5446 was the same as Oregon 91G. Average root rot scores were Oregon 54 (5402) 3.0, Oregon 91G 3.5, and 5446 4.5. OSU 5256 and 5421 also scored 4.5.
- C. Newer breeding material involved in the program included many new small sieve crosses, including 5446 x 76-110, and populations from intercrosses of OSU standard bush Blue Lake lines.

7. Summary:

In replicated trials, Oregon 54 (5402), OSU 5416, OSU 5256, and OSU 5421 produced higher \$/acre value than Oregon 91G, even though adverse effects of hot weather on these lines were apparent in most trials. OSU 5421 was the most tolerant of heat, apparently, and produced the highest yields and return. Small sieve line OSU 5446 compared well in \$/acre with Dandy, 76-110, Teseo, and Banquet. OSU 5446 produced the highest season average of the small sieve types, but it tends to be higher in percentage of 4-sieve pods (compared to 3-sieve) than Dandy and 76-110.

¹Based on a value of \$275 for 3 and 4 sieve pods; \$127 for 5 and 6 sieve pods. 1 and 2 sieve pods excluded.

²Average \$/acre is a rough estimate because of non-uniform number of trials and maturities included.

³Selected best values for comparison. Usually the same value used for Analysis of Variance in Tables 1-3.

¹2 sieve values calculated as 50% of the combined 1 + 2 sieve weights from grader.²Total weight of graded beans, including sieve sizes 1-5.³\$/acre based on \$300/ton for 2-4 sieve; \$120/ton for 5 sieve.

* Harvest which produced the highest tons/acre of 3-sieve pods.

Harvest which produced the highest percentage of 3-sieve pods.
