# Report to the Oregon Processed Vegetable Commission <br> 1999-2000 

1. Title:
2. Project Leaders:

Cooperator:
3. Project Status:
4. Project Funding:

Green Bean Breeding
James R. Myers, Horticulture
Brian Yorgey, Food Science and Technology
David Mok
Terminating 30 June, 2000
\$48,186 breeding
\$7,993 processing
\$56,179 total

Breeding funds were used for a major portion of the support of a vegetable breeding technician, student labor, supplies, and research farm expenses. A plot thresher was also purchased. Processing funds were used for processing samples of experimental beans, laboratory analysis, and for student labor.
5. Objectives:
i. Breed Bush Blue Lake green bean varieties with high economic yield.
ii. Improve pod characteristics including straightness, color, smoothness, texture, flavor and quality retention, and combine with delayed seed size development.
iii. Incorporate white mold resistance, and improve root rot tolerance while maintaining resistance to bean common mosaic virus.
iv. Initiate populations to facilitate molecular marker assisted selection of desirable horticultural traits.
v. Evaluate novel genetic traits of potential benefit.

## 6. Report of Progress:

Bean breeding lines and commercial varieties were tested in replicated trials planted 22 April, 24 May, 1 June, and 14 June. The advanced trials planted 22 April and 24 May consisted of three check varieties and seven advanced lines planted in two row plots replicated six times. The 1 June trial was a preliminary trial, and consisted of one row per entry replicated six times. This trial had four check varieties and 21 experimental lines. The 14 June trial consisted of five check varieties (two full sieve green beans, one small sieve green bean, one wax bean and one Romano bean), six OSU lines, and 13
commercial entries (two wax beans and two Romanos). A preliminary trial was planted in early May, but was abandoned because of severe Dual injury from fall application of the herbicide to control yellow nutsedge. An additional advanced trial was planted in late June because of concerns with stand problems in the second advanced trial. However, we decided to proceed with evaluation of the second advanced trial. Therefore, the last advanced trial was not harvested because we already had data from two advanced trials in 1999.

For all trials, five-foot sections of row were handpicked on each harvest date in each of four replications. In most cases, three harvests on alternate days were made to obtain a range of maturity. Replications were combined for grading.

Samples were canned and frozen at Food Science and Technology for evaluation by industry representatives in February. Processed quality data will be published in a separate report.

Data from replicated trials are summarized in Tables 1-10 and Figures 1-11. The season began rather cold and rainy, which resulted in a long maturation period (about 90 days) and lack of concentrated set in the first trial. The growing season in general was very mild with little evidence of split sets due to high temperatures.

For full sieve advanced lines overall, Oregon 54 had higher \$/A than Oregon 91G (see summary table below, tables $1-4,6$ ), but not significantly so. Among the experimental lines, OSU 5651 continued to have the highest $\$ / A$ values followed by OSU 5635. Both lines were significantly higher than Oregon 91G and OSU 5630. Although not significantly different than Oregon 91G, OSU 5630 had lower \$/A values for trial averages, and selected harvests. In general, OSU 5630 and OSU 5669 show greatest similarity to Oregon 91G for field performance. OSU 5630 has pod color similar to Oregon 91 G , but pods are smoother and straighter. OSU 5669 has significantly better pod color as well as straighter and smoother pods. OSU 5416, OSU 5635, and OSU 5651 are most similar to Oregon 54 with straighter and smoother pods. In 1998, OSU 5630 and OSU 5651 showed the greatest heat tolerance, while OSU 5635 was worst, although these results may be compounded with maturity.

| Season average \$/A based on |  |  |  |

| ${ }^{y}$ The harvest selected as best for comparison and used for analysis of variance at 50\% 1-4 sieve in tables 5, 6 and 10. |  |  |  |

Four year averages for yield and \$/A values are shown below for full sieve advanced lines and checks. For the overall average, only OSU 5651 was significantly higher than Oregon 91 G and OSU 5630. Trends in the data generally suggest the following order: OSU 5651>Oregon 54=OSU 5416=OSU 5635>Oregon 91G=OSU 5630=OSU 5669. OSU 5635 appears to have yield stability in that it performed consistently in most years, whereas other high yielding cultivars varied from year.

${ }^{2}$ Average of $5,5,5$ and 4 trials in 1996, 1997, 1998 and 1999 respectively. Based on field yields of 2-6 sieve beans.

Other standard sieve lines: One preliminary trial was grown this year with four standard sieve lines included in addition to the advanced lines (tables 3-6). OSU 5641 and OSU 5643 have been tested for two years now. Both had higher yields than Oregon 91G, and OSU 5641 out yielded Oregon 54 when adjusted to $50 \% 1-4$ sieve. In the field, OSU 5641 showed greater lodging, probably associated with higher yield. Pod quality of OSU 5641 was not as good as OSU 5643, but was comparable to Oregon 91G. Last year, OSU 5643 had the best performance of the group. OSU 5641 and OSU 5643 tend to become seedy at 50\% 1-4 sieve, and may be best handled as an intermediate sieve bean. OSU 5698 has been grown for several years. It is similar to Oregon 91G in yielding ability, but has better pod quality. It also had better heat tolerance than most lines in 1998. A decision on whether to keep this line should be made after frozen and canned product
evaluation. OSU 5709 was grown for the first time this year. It had a very concentrated set, very smooth pods with color slightly lighter than Oregon 91G. It was also significantly lower yielding than all other entries. Because pod characters are not significantly better than the checks, this entry will not be grown next year.

Small Sieve Beans: Trials were concentrated on comparing OSU 5613 to Medinah and Minuette this year (tables 7 \& 8). Based on season averages, OSU 5613 had higher \$/A value than either Medinah or Minuette, although the difference was not statistically significant (table below). Based on a five year average, OSU 5613 had higher yield and \$/A value than Minuette. The difference was statistically significant for yield but not for \$/A. OSU 5613 seems to perform particularly well during the cool and wet conditions typical of early spring plantings as can be seen in tables 7 and 8. In later-season trials, Medinah and Minuette sometimes have higher yields and \$/A values.

| ${ }^{2}$ Average of 2, 5, 4,5 and 4 trials in 1995, 1996, 1997, 1998 and 1999 respectively. |  |  |  |  |  |  |

OSU 5747, OSU 5803, and OSU 5804 were tested in 1998 and 1999 (see table below). The three lines produce mostly 3 and 4 sieve beans at optimum harvest. In comparison with OSU 5613, OSU 5747 was lower yielding. It also had very smooth, long, but lighter colored pods, and is probably not worth further testing. It should be crossed to OSU 5446 derived lines to improve pod length. OSU 5803 and OSU 5804 had yields and $\$ /$ A values that were comparable or superior to OSU 5613. OSU 5804 in particular has had consistently high yields. These lines are sisters, and were derived from the cross OSU 5446 X Oregon 91G. In comparisons with OSU 5446 and other checks, they generally
had longer pods than OSU 5446 with OSU 5804 having longer pods than OSU 5803. Pod color was equal to or better than Oregon 91G. OSU 5803 had round pods while OSU 5804 had slightly oval pods. Both lines have potential to fill the niche of a 4 -sieve bush blue lake type. OSU 5804 at least should be retained for further testing.

| Two year average for small sieve |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: |
| beans |  |  |  |  |  |

Small sieve beans tested for the first time this year included OSU 5723, OSU 5842, OSU 5844 and OSU 5860 . OSU 5723 had a significant percentage of 5 -sieve pods, although most pods were in the 4 -sieve class at optimum harvest. Pods were very dark green, straight and smooth. The line was late and had a split set, but still managed yields comparable to Minuette and Medinah (table 8). OSU 5842 and OSU 5844 are sister lines with high yields and \$/A values. Both are OSU 5446 type with significantly longer and straighter pods. Color of OSU 5842 is comparable to OSU 5446 whereas that of OSU 5844 may be lighter. Both should be tested again next year. OSU 5860 is another 4 -sieve type. Yields were low in this trial and pod quality was marginal, although optimum harvest may have been missed. A decision concerning retention of this line in the program should be made after processed product evaluation.

Commercial Bean Trial: This trial had lush growth leading to indeterminancy and white mold infection. In addition, bean lines became seedy without pods fully sizing. In general, OSU lines had higher yields than other green bean lines. Some of the commercial lines, particularly 4-sieve lines, had high \$/A value. Both SB 4218 and SB 4248 had color as good as or better than 91 G . Other green bean lines tended to be too light. Among the wax beans, both experimental lines had better color in small sieve sizes than Indy Gold. Klondyke is apparently a standard sieve size bean, but 5 -sieve size pods were seedy, and no 6 -sieve pods were produced. It was the highest yielding of the wax beans. Among small sieve size beans, Proton produced exceptionally high yields for a 2sieve bean. Among Romano bean lines, Tapia had yields that equaled Roma II where as Oja had significantly higher yields. Tapia had better color and maturity uniformity than Roma II while Oja was later and less uniform in maturity.

Root rot and white mold trials: A root rot trial containing 90 checks and breeding lines was grown in two replicates and evaluated (table 11). Overall, disease incidence did not seem as severe this season, because most OSU breeding lines and checks had low to moderate disease incidence. Medinah was severely stunted in this trial (as was Minuette) and receive a root score of 4.5 and 5 . Seventy breeding and germplasm lines were grown
in a white mold nursery. Growth in the field was lush and disease incidence was extremely severe (for example, Oregon 54 had a score of 9 on a 1-10 scale). The best Oregon blue lake line is B7354-6-2-1 with an average score of 2.5 . This a low yielding flat-podded line, but may be a source of useful resistance when crossed into a better blue lake type.

Development and evaluation of new materials: Selection continues in the Oregon blue lake X Minuette crosses to obtain lines with improved architecture. Many selections from these crosses also have extremely dark green pods. This material is now in the $\mathrm{F}_{5}$ generation and approaching homozygosity. Other crosses have been made for white mold resistance, additional sources of improved architecture and general population improvement within the blue lake background.

Molecular Marker Laboratory: Recombinant inbred lines developed by single seed descent from crosses between OSU varieties and lines Maxima or Minuette are now in the $\mathrm{F}_{5}$ generation. This summer, we evaluated the 200 recombinant inbred lines from the cross OSU 5630 X Minuette and its reciprocal for morphological and horticultural traits. We have begun to map RAPD markers in this population with the objective of developing a linkage map with important traits mapped. RAPD markers have also been used to characterize a diverse group of snap bean lines for characterization of genetic relationships.

Bean seed thresher: A comparison of field emergence of OSU 5635 threshed by hand, and threshed with the Alamco small plot thresher showed that the machine threshed seed had about a $10 \%$ reduction in emergence compared to the hand threshed seed $(69.5 \%$ vs $79.5 \%$ ) for seed planted during the early season. Such a reduction is acceptable for propagation of breeding lines (and may be considered a selection tool for resistance to mechanical damage), but would not be acceptable for production of seed for nursery plantings. This year, further refinement of adjustment of the thresher has resulted in seeds with less damage.

Small scale processor evaluation: Several lines were grown on small acreages for processing evaluation. OSU 5630 performed well compared to Oregon 91G (see table below) for both yield and \$/A. While OSU 5651 had higher yield, $\$ / \mathrm{A}$ was lower than adjacent Oregon 91G. OSU 5651 seemed rather indeterminate in this planting, which may be related to the lower \$/A received for this line. OSU 5613 was also grown in an on farm trial, where it produced a yield of $6.5 \mathrm{~T} / \mathrm{A}$ (gross).

| Line | Location | Acres | Gross T/A | Net T/A | \$/A |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Oregon 91G | 1 | 11.0 | 10.6 | 9.5 | $\$ 1,741$ |
| OSU 5630 | 1 | 8.0 | 11.0 | 9.8 | $\$ 1,778$ |
| Oregon 91G | 2 | 17.4 | 6.6 | 6.6 | $\$ 1,344$ |
| OSU 5651 | 2 | 0.7 | 8.3 | 7.5 | $\$ 1,319$ |
| OSU 5613 | 3 | 24.7 | 6.5 | 5.7 | $\$ 1,252$ |

Plans for release: Given the accumulation of positive data, OSU 5613 should be released to the trade this spring. It is less easy to determine if other advanced lines should be released. While OSU 5630 has acceptable performance and better pod quality than Oregon 91 G , one seed company has found the line to produce an excessive number of off-types. I am waiting to hear from other seed companies before deciding on release. Other lines lack sufficient on farm testing. OSU 5651 should be tested again in larger acreages, and OSU 5635 and OSU 5669 should be grown on farm.

## 7. Summary:

Eighteen OSU lines were evaluated in replicated handpicked yield trials planted over the period 22 April to 14 June. Minuette was included as a small sieve check in all trials and Medinah was included in some trials. Sixteen commercial varieties (including standard and small sieve green beans, wax beans, and Romano beans) were also evaluated. Continuing a trend from previous years, OSU 5630 and OSU 5669 had yields similar to or better than Oregon 91G with superior pod quality. OSU 5651 has good pod quality, very high yields, and appears from this year's data to have a more concentrated set than that of Oregon 54. OSU 5635 has yields similar to or slightly less than Oregon 54 and good pod quality. It also appears to have yield stability over environments. Among small sieve lines, OSU 5613 had a superior field performance compared to the checks, particularly in early season plantings. OSU 5613 has pod quality similar to Oregon 91G with yields comparable to Minuette. White mold and root rot trials were continued with the identification of several lines with resistance. Crosses with new white mold resistant lines were made, and populations were advanced in the field. Recombinant inbred populations have been developed and we are beginning to develop a genetic map. Three OSU lines were evaluated on farm in small-scale processor trials.

${ }^{\text {z }}$ Dollar values were calculated using the weight of graded beans, based on a value of $\$ 239$ for $2-4$ sieve pods; $\$ 108$ for 5 and 6 sieve pods. Yield of 2 sieve pods was obtained by taking $75 \%$ of the combined graded $1+2$ sieve pods. Values will be lower than those reported in Table 5 because some beans are lost in the grading process and because 1 sieve pods are excluded.
${ }^{y}$ Average \$/acre is a rough estimate because of non-uniform number of harvests included.

${ }^{2}$ Percent calculated as \% of total of 2-6 sieve beans. 2 sieve values calculated as $75 \%$ of the combined $1+2$ sieve weights from grader.
${ }^{\mathrm{x}}$ Total weight of graded beans, including sieve sizes 2-6. Values will be lower than those reported in Table 7 because some beans are lost in the grading process and because 1 sieve pods are excluded. Occasional 6 sieve are not shown in table, but are included in graded total.
${ }^{\mathrm{w}} \$ /$ acre based on $\$ 302 /$ ton for 2-4 sieve; $\$ 0 /$ ton for $5-6$ sieve.

${ }^{\text {z Based }}$ on one selected harvest for each variety in each trial, which was the last harvest, (highest $\$ / A$ ) unless sieve size distribution or notes indicated the variety was overmature (marked with * on Table 7). Yields are field yields of 2-6 sieve beans.
${ }^{y}$ Overall average is a rough estimate because of non-uniform number of trials included.

${ }^{2}$ Percent calculated as \% of total of 2-6 sieve beans.
${ }^{\mathrm{y}} 2$ sieve values calculated as $75 \%$ of the combined $1+2$ sieve weights from the grader.
${ }^{\times}$Total weight of the graded beans, including sieve sizes 2-6. Values will be lower than those reported in Table 9 because some beans are lost in the grading process and because 1 sieve pods are excluded.
${ }^{w} \$ /$ acre based on $\$ 239 /$ ton for 2-4 sieve and $\$ 108 /$ ton for $5-6$ sieve for full sieve and 4 sieve beans; and $\$ 302 /$ ton for $2-4$ sieve and $\$ 0 /$ ton for $5-6$ sieve for small sieve beans.
