

# Predicting Plant-Pollinator Interactions in Montane Meadows Using a Multinomial Model

Ivan Pyzow and Kaitlin Horan  
EISI REU Summer 2014  
August 21, 2014

# Definitions

**pollinator's preference** (for a flower): a value from 0 to 1 that quantifies the level of interactions with a flower, independent of the flower's relative abundance. In other words, we use preference to refer to all factors that influence flower selection besides frequency-dependence, which might be the nectar resource of the flower or an innate bias by the pollinator.

**pollinator's preference list**: a list of a pollinator's preferences for different flowers, scaled so that the list sums to 1.

# Our Questions

- 1) Do the pollinators in this study exhibit flower selection strategies that are strictly frequency-dependent?
- 2) For each pollinator, how accurately does our optimized preferences list predict the observed interactions?

# Our Hypotheses

- 1) We anticipate that pollinators do not exhibit a strictly frequency-dependent flower selection strategy.
- 2) We anticipate that our optimized preference list will return p-values greater than 0.95 when using a test of goodness-of-fit.

Pollinator	Description	Number of Sightings (Note this is different from the total number of interactions as the same pollinator might have had multiple interactions)
<i>Apis mellifera</i>	Social bee	4101
<i>Bombus mixtus</i>	Social bee	2835
<i>Epicauta puncticollis</i>	Beetle	1534
<i>Bombus bifarius</i>	Social bee	945
<i>Muscoid genus 3</i>	Fly	731
<i>Bombylius major</i>	Beefly	677
<i>Eristalis hirtus</i>	Syrphid	572
<i>Coccinella septempunctata</i>	Ladybird	459

$$L(d_1, d_2, \dots, d_n) = \prod_{j=1}^m c_j \left( \prod_{i=1}^n \lambda_{ij}^{b_{ij}} \right)$$

where

$m$  = number of meadow-watch-years

$n$  = number of flower species

$a_{ij}$  = abundance of flower  $i$  on meadow-watch-year  $j$

$b_{ij}$  = number of interactions between pollinator  $p$  and flower  $i$  on meadow-watch-year  $j$

$d_i$  = desirability of flower  $i$  for pollinator  $p$

$$\lambda_{ij} = \frac{d_i a_{ij}}{\sum_{k=1}^n d_k a_{kj}}$$

$$c_j = \frac{\left( \sum_{h=1}^n b_{hj} \right)!}{\prod_{h=1}^n (b_{hj}!)}$$

# Our Multinomial Model

# Maximizing the Likelihood Function

To generate our optimized preferences lists:

- input flower abundances and number of interactions by a given pollinator for each flower species
- minimize negative log likelihood
- output preference list

To calculate expected interactions:

- input flower abundances and pollinator preferences list

Top ten desirabilities of flower species for *Apis mellifera*

Top ten desirabilities of flower species for *Bombus mixtus*

Top ten desirabilities of flower species for *Eristalis hirtus*

Top ten desirabilities of flower species for *Bombylius major*

# The Five Tests

For each test, we predict interactions and then test how close the expected interactions are to the observed interactions.

- 1) Chi-squared with uniform preferences list for each watch-year
- 2) Chi-squared with uniform preferences list for all three years
- 3) Chi-squared with optimized preferences list for each watch-year
- 4) Chi-squared with optimized preferences list for all three years
- 5) Likelihood ratio test with uniform preferences list and optimized preferences list for all three years

# Tests 1 and 2

1. Compares interactions predicted by uniform preferences list to observed interactions for each watch-year:

We reject the uniform preference list for all four insects.

2. Compares interactions predicted by uniform preferences list to observed interactions for all 3 years:

Again, we reject the uniform preference list for all four insects.

## Test 3

3. Compares optimized preferences list for each watch-year.

Most watch-years are rejected, except for *Eristalis hirtus*.

**APIS MELLIFERA**

Watch-Year	p-value
2011 1	0.108
2011 2	0.527
2011 3	0
2011 4	0
2011 5	0
2011 6	0
2012 1	0.043

2012 2	0
2012 5	1
2013 1	0
2013 2	1
2013 3	0.994

**ERISTALIS HIRTUS**

Watch-Year	p-value
2011 2	0
2011 3	0
2011 4	0
2011 5	0.762
2011 6	0.131
2012 1	0.974
2012 2	0
2012 3	1
2012 4	0.639
2013 7	0.986

Top ten desirabilities of flower species for *Apis mellifera*

Top ten desirabilities of flower species for *Bombus mixtus*

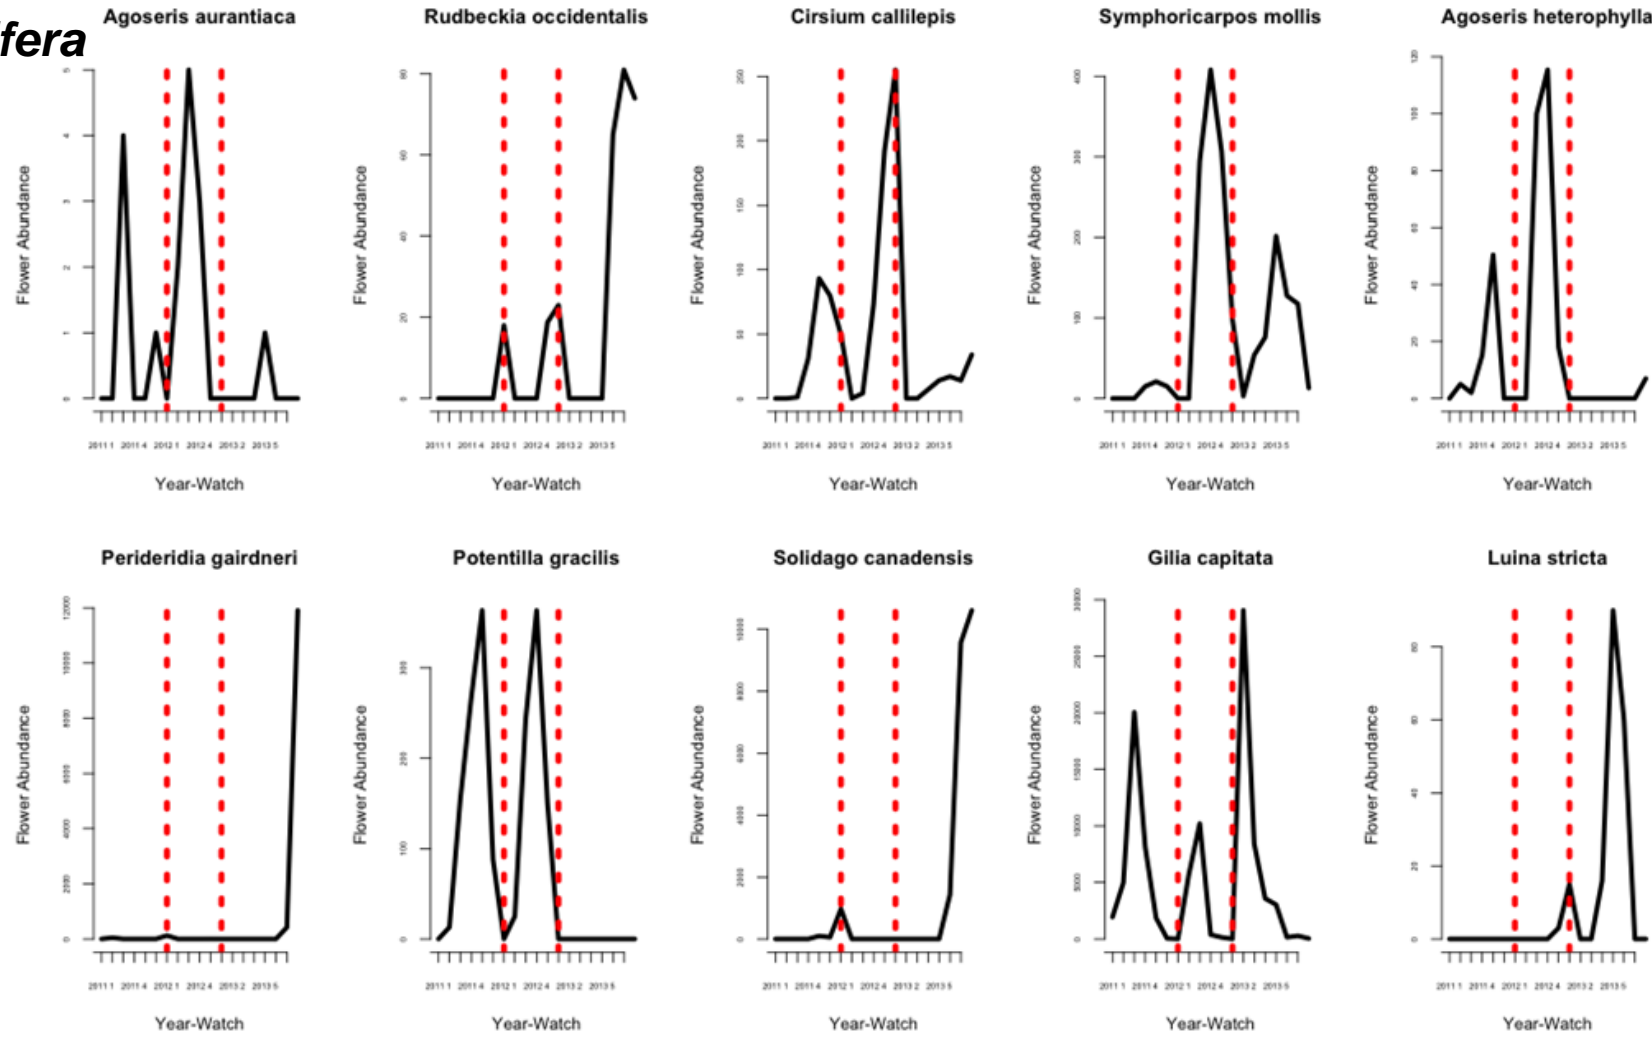

Top ten desirabilities of flower species for *Eristalis hirtus*

Top ten desirabilities of flower species for *Bombylius major*

# *Apis mellifera*

# *Eristalis hirtus*

## Test 4

4. Compares optimized preferences list against observed interactions for all 3 years:

We reject the optimized preferences list for all insects.

# Eristalis hirtus - Watch #1

Expected

Observed

## Eristalis hirtus - Watch #2

## Eristalis hirtus - Watch #8

## Eristalis hirtus - Watch #9

Expected Observed

# Test 5

Since both the uniform preferences list and the optimized preferences list were rejected by our earlier tests, we can compare them in one statistical test to determine which is more accurate. We use the likelihood ratio test.

Our resulting p-value for the test is  $0^*$ , so we reject the uniform preferences list, and conclude that our optimized preferences list is more accurate.

# In Conclusion

Pollinators do not have flower selection strategies that rely solely on flower frequency.

Our optimized preferences list, though being rejected by the chi-squared test for goodness-of-fit, still predicts pollinator interactions better than the uniform preferences list.

# Further Research

What factors influence preferences for flowers?

Do these preferences change over time?

How can we augment our model to more closely resemble what is actually occurring in the meadows?
